# BI-DIRECTIONAL COMMUNICATION INTERFACE FOR MICROPROCESSOR-TO-SYSTEM/370

National Aeronautics and Space Administration  
Langley Research Center  
Hampton, Virginia  
Grant NGR 36-009-017

## I. INTRODUCTION

This paper documents the design and operation of a bi-directional communication interface between a microcomputer and the IBM System/370. The hardware unit inter-connects a modem to interface to the S/370, the microcomputer with an EIA I/O port, and a terminal for sending and receiving data from either the microcomputer or the S/370. Also described is the software necessary for the two-way interface. This interface has been designed so that no modifications need to be made to the terminal, modem, or microcomputer. This unit is designed to upgrade an uni-directional interface already in use [ 1 ]

## II. INTERFACE DESCRIPTION: HARDWARE

Figure 1 shows the paths of signals between the microcomputer, the modem, and the terminal. The hardware interface consists of a four-pole, three-position switch and cables and plugs to connect the switch box to the other devices. All signals are assumed to be RS-232C (EIA standard).

In switch position 1, the microcomputer is connected directly to the terminal; all communications are between these two only. The modem is isolated in this position and it is not necessary to have it connected if no communication to the S/370 is desired. In position 2, the serial out from the keyboard is routed to the modem for communicating to the S/370. The serial out from the modem goes to the terminal and the serial in of the microcomputer. In this position, it is possible to send commands and receive responses from the S/370, while the microcomputer reads the data sent by the S/370. Thus it is possible to load a program into the microcomputer by displaying the object file on terminal. It is necessary to switch to position 1 and issue the microcomputer load command prior to typing the file. Position 3 on the switch box connects the serial out from the modem to the terminal and to the serial in on the microcomputer. In addition, the serial out from the microcomputer is sent to the modem. Here, the microcomputer communicates directly with the S/370, the terminal always displays the response sent by the S/370. With proper positioning of the half-duplex/full-duplex switches on the terminal and modem, the responses from the microcomputer may also be displayed. Note that the serial-out from the terminal is isolated, thus it may be necessary to start a program on the microcomputer by pressing the NMI (non-maskable interrupt) switch on the switch box.

Table 1 lists the connection used on the terminal and modem. Connections for RS-232C are made through 25-pin D-connectors. Data terminal equipment (DTE) devices are supplied with a male (DB-25P) connector while data communication equipment (DCE) devices are supplied with a female (DB-25S) connector. Figure 2 shows the detailed routing of connections from the connectors on the terminal and modem through the switch box.

### III. INTERFACE DESCRIPTION: SOFTWARE

Full utilization of the bi-directional interface requires a set of programs to be run simultaneously on the microcomputer and the S/370. Figure 3 shows a block diagram of how the programs would operate for a typical application. Some points to be considered in writing the interface software are:

- a. Most microcomputers store character data internally as ASCII.
- b. Serial communications between devices are generally in ASCII format.
- c. The I/O routines for the S/370 expect to receive ASCII which is then converted to EBCDIC, which the S/370 uses for internal storage of character data.
- d. The Conversational Monitor System (CMS) portion of the VM/370 operating system is line-oriented, i.e., no system action is taken until a carriage return (hex OD) is received.
- e. The S/370 issues a prompt when ready for another line.

A typical application for which this interface has been used is transmitting data collected by the microcomputer on a cassette tape to the S/370, where it is stored on a disk file for further processing. The sequence of events is as follows: the data to be transmitted is stored in a buffer in the microcomputer's memory. Generally, 80 characters comprise one line. Note that one byte consists of two four-bit hexadecimal numbers, each of which is converted to ASCII. Thus if 80 characters are to be sent, the buffer is 40 bytes long. After 80 characters are sent, a carriage return (hex OD) is sent. The S/370 does the ASCII-to-EBCDIC conversion and places the EBCDIC characters in a user buffer in the S/370 memory. When the S/370 is ready to receive another line, it sends a series of control characters. The microcomputer reads and recognizes these control characters as the prompt signal to send another line. The sequence of control characters currently sent by S/370 is shown in Figure 4.

Appendix A gives a listing of a MOS Technology 6502 microcomputer program (intended to be run using the 'Super-Jolt' micro unit) for reading 40 bytes of data from a Memodyne digital cassette tape unit and sending these to the S/370. The data to be sent are packed BCD numbers; i.e., one BCD digit occupies four bits, two BCD numbers are contained in one byte. Each BCD digit is sent as ASCII by the 'output byte' routine in the microcomputer monitor program (at address 72B1 (hex) in the Super-Jolt (TM) monitor). A carriage return is sent at the end of the line with a call to the WRT routine at address 72C6 (hex).

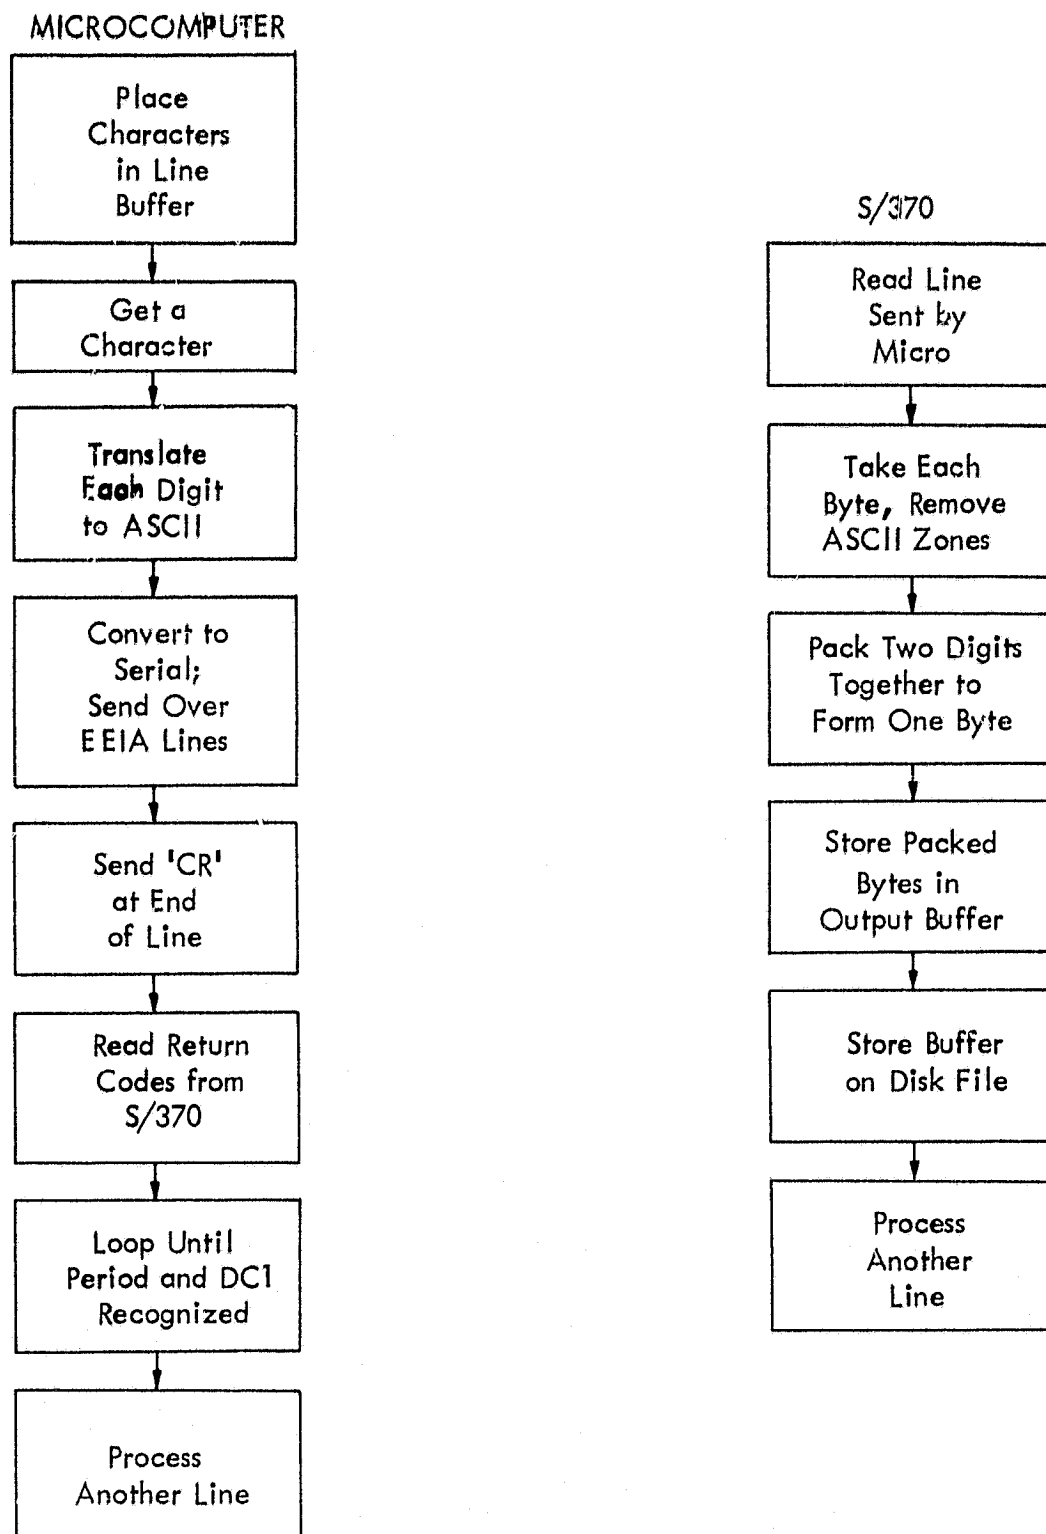

Figure 3. Control Program Flow Charts.

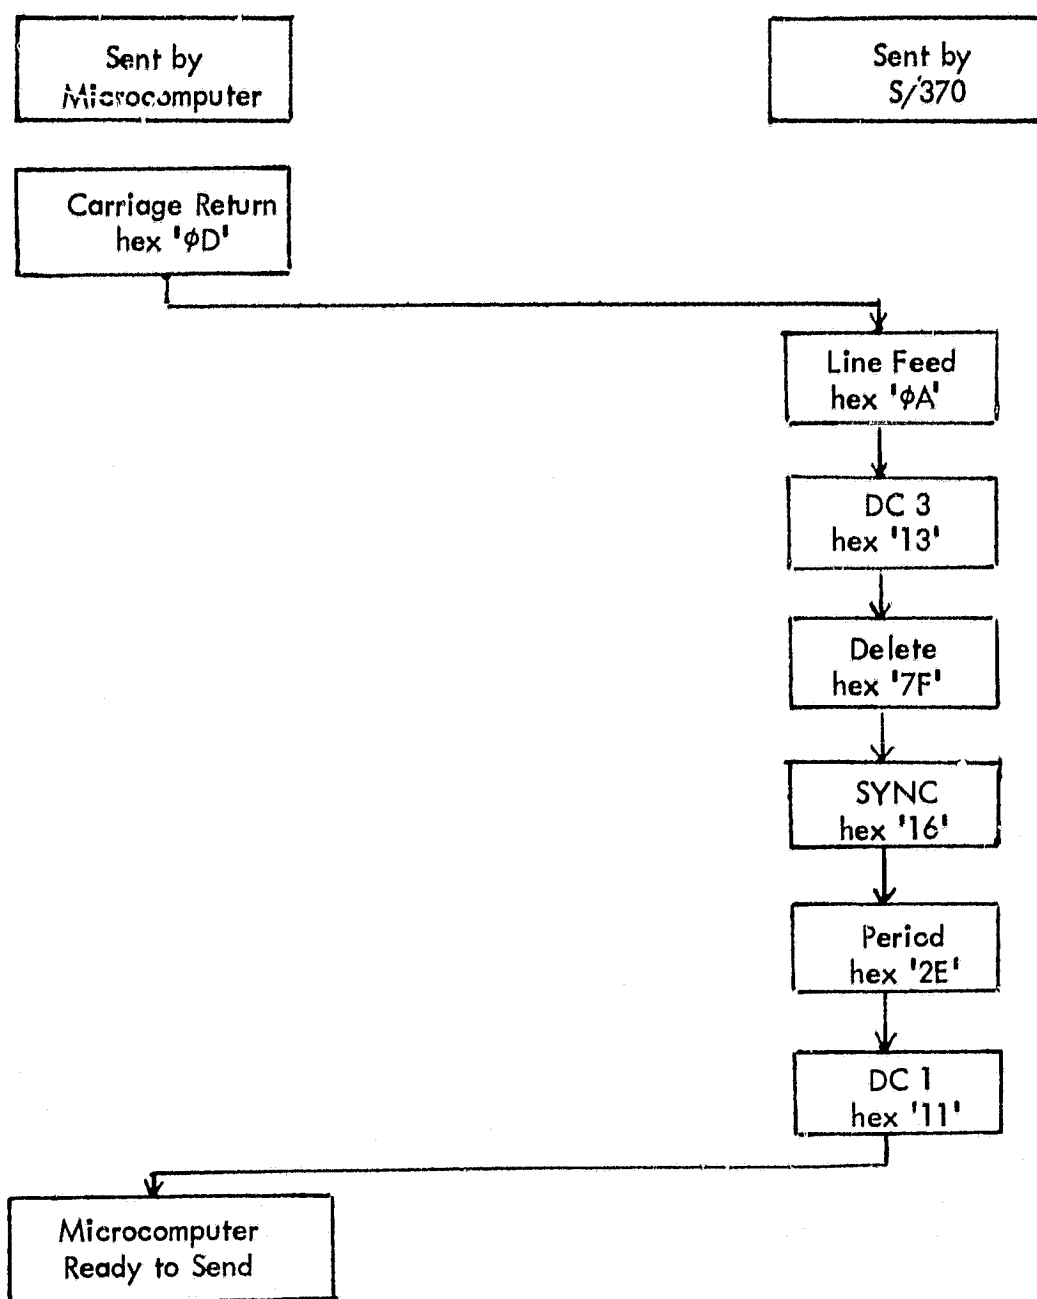

Figure 4. Control Characters Sent by S/370 After Receiving Carriage Return.

Program lines 1 to 78 are initialization steps used for the Memodyne interface hardware and to position the tape properly. Lines 79 to 91 constitute the main part of the program which builds up the 40-byte buffer then sends the buffer to the S/370. This part loops continuously whether or not any data is received. The operator should monitor the operation to stop the program when all the data has been transmitted. Subroutine READ is called to read a byte from the tape unit. Subroutine W370 sends the 40-character buffer to the S/370, sends a carriage return, then looks for a period (hex 2E) followed by a DC-1 (hex 11). If this sequence is not done, the S/370 issues a read-error message. When these two characters are received, control is passed back to the main program sequence.

Subroutine RDT is a modification of the RDT routine at address 72E9 in the Jolt monitor. Most serial-read routines on microcomputers are full-duplex; as each bit is received, it is echoed back out to the sending device. However, the S/370 can receive half-duplex only. Thus it is necessary to change the interface method through the modem or to re-write the read routine so that the received bits are not echoed by the microcomputer. This is the purpose of having a separate read routine. If this is not done, read-errors result. The program presented here is shown to illustrate one application of the bi-directional interface. Other uses on other microcomputers would still use the same basic philosophy.

The companion program that is run on the S/370 is shown in Appendix B. This program is written in IBM 360/370 assembler language [ 2 ] using standard CMS I/O routines. Again this program illustrates the application of sending data to the S/370 for storage on a disk file.

The data is read 80-bytes at a time, each BCD character in its ASCII format. Each character read is stripped of the upper four-digit mask and is repacked. This is done by the translate instruction at line 88 and the PACK instruction at line 90. Since one record produces only 40 packed BCD digits, two lines are read before one 80-byte record is written to the file. A blank line or an incomplete line is filled to the end with zeros. Each time a record is written, a counter is incremented which is printed at the end of program execution.

#### IV. INTERFACE OPERATION

The example of transmitting data from the microcomputer to the S/370 will be continued here to show how the interface may be operated. After the interface is properly connected, power should be applied to all units. At this point it is usually necessary to load the microcomputer with a program stored on a disk file. Thus the switch box should be set to position 2 and the appropriate CMS LOGON procedure performed. When the microprocessor object code is ready for transmittal (through editing, assembling, simulating, etc.) the switch box should be set to position 1, the microcomputer reset button pushed, and a carriage return or other appropriate

key to reset the microcomputer typed. Then issue the proper command to set the microcomputer for loading hexadecimal data over its serial lines. The switch box is then set back to position 2 and the appropriate command is issued to the S/370 to load the microcomputer with the object file. Next, the unit is switched back to position 1 to verify correct loading, initialize any memory locations and set up the NMI vector address to the start of the program. Now the switch box is placed in position 2 and the program to receive the data is started and then the unit is set to position 3 and the NMI button pressed.

As operation commences, the prompting period and any other responses from the S/370 will be displayed on the terminal. Depending on the setting of the half-duplex/full-duplex switches on the terminal and modem, data sent by the microcomputer will also be displayed on the terminal.

When the operation is finished, the unit may be set to position 2 to stop the S/370 program then position 1 to stop the microcomputer program.

#### V. SUMMARY

A discussion was presented here of an interface unit and software procedures to allow two-way communication between a microcomputer and a central computer. This can be used for two-way data transmission, control and other applications where bi-directional communications are necessary. As an aid to setting up the software for other computer systems, ASCII [3] and EBCDIC [4] tables are given in Tables 2 and 3.

B. Program Listing for S/370 Control Program.

TITLE 'UNLOAD\$\$: READS RECORDS FROM MEMODYNE/MICROCOMPUTER IN\*  
TERFACE AND STORES ON DISK.'

PRINT NOGEN

SPACE

```
*****
*
* THIS PROGRAM IS DESIGNED TO BE RUN ON THE S/370 IN CON-
* JUNCTION WITH THE MICRO 'UNLOAD' PROGRAM AND THE MEMODYNE/
* MICROCOMPUTER HARDWARE INTERFACE. RECORDS READ FROM
* TAPE BE THE MICRO ARE SENT TO THE 370 IN ASCII, CP THEN
* TRANSLATES THESE TO EBCDIC WHICH MUST BE TRANSLATED
* BACK TO HEX BY THIS PROGRAM. 80 BYTES ARE SENT AT A
* TIME (40 EQUIVALENT HEX CHARACTERS) AND 80 HEX CHARACTERS
* ARE STORED ON THE DISK FILE.
*
* J. P. FISCHER 08/1980
*
```
